

A First Lean Formalization Audit of the IUT III Corollary 3.12 Corridor

IUT Lean formalization project

May 28, 2026

Abstract

This note records the present state of a Lean formalization of a narrow part of Mochizuki’s inter-universal Teichmüller theory: the passage from IUT III, Theorem 3.11 to Corollary 3.12, with attention to the Scholze–Stix objection. The current Lean code proves conditional route theorems and obstruction lemmas. It does not prove Corollary 3.12 and does not refute it. The main formal result so far is that a nonarchimedean (Ind3) entry, together with explicit Hodge/SHE square-weight transport data, feeds a hull/log-volume q -to- Θ comparison, while several simplified collapse mechanisms are rejected by Lean.

1 Scope

The review used the local Markdown conversions of IUT I–IV, Mochizuki’s 2026 formalization note, and the Scholze–Stix note. The relevant source passages are:

- IUT I: initial Θ -data, prime strips, Hodge theaters, and non-scheme-theoretic Θ -links.
- IUT II: Hodge–Arakelov evaluation, theta values of shape q^{j^2} , multiradiality, and Gaussian monoids.
- IUT III: Theorem 3.11; Corollary 3.12, especially Steps (x) and (xi); Remarks 3.12.2 and 3.12.3.
- IUT IV: later explicit log-volume estimates and Diophantine consequences.
- Scholze–Stix: the ordered real-line identification problem in their Section 2.2.
- Mochizuki 2026: the “3.11.5 $\Rightarrow$ 3.12” fourth-triangle decomposition.

2 Mathematical Target

IUT III Step (x) treats procession-normalized log-volumes as invariants for (Ind1) and (Ind2), and turns (Ind3) into an upper inequality. Step (xi) then uses the multiradial construction, IPL, SHE, holomorphic hulls, determinants, and log-volume to place the q -pilot log-volume in an upper ray controlled by the Θ -pilot log-volume:

$$-|\log(q)| \in \mathbb{R}_{\leq -|\log(\Theta)|} \quad \Rightarrow \quad -|\log(q)| \leq -|\log(\Theta)|.$$

Mochizuki’s 2026 note isolates the final comparison as:

$$\text{Theorem 3.11} \xrightarrow{\text{APT+IPL}} \text{“3.11.5”} \xrightarrow{\text{SHE+IPL}} \text{Corollary 3.12.}$$

The present formalization targets only this corridor, not the full construction of Theorem 3.11.

3 Dispute Interface

Scholze–Stix require explicit bookkeeping for all ordered one-dimensional real vector spaces. Their pressure point is that the Θ -side concrete objects carry j^2 -scaled degrees, while a consistent identification of the real lines appears to leave no room for inserting all these scalars.

The formalization therefore separates:

representative j^2 data		raw real equality
balanced sign-compatible data	and	transported equality
aggregate averaged data		matched transport scales
final hull/log-volume data		cancellable ordered-line comparison.

This separation is the main correctness guard in the current code.

4 Lean Coverage

The relevant implementation is in

`Iut/Stage1/IUTStage1Source.lean` and `Iut/Stage1/IUTStage1Experiments.lean`.

The code currently covers:

- labeled real-line copies and positive-scale transports;
- a finite $\mathbb{F}_\ell$ -label model with representative square weights $j \mapsto j^2$;
- a representative pilot-degree profile $\deg(\Theta_j) = j^2 \deg(q)$;
- proof that one label-independent scale cannot absorb all representative j^2 scales in this model;
- proof that, for nonzero $\deg(q)$, one label-independent scale cannot account for all representative Θ_j -degrees;
- proof that the raw representative j^2 theta-degree rule does not descend to the sign quotient $|F_\ell| = F_\ell/\{\pm 1\}$ when $\deg(q) \neq 0$;
- an absolute-label exponent on $|F_\ell| = \{0\} \cup F_\ell^\times/\{\pm 1\}$ which agrees with j^2 for the canonical representatives $0 \leq j \leq (\ell - 1)/2$, and the corresponding theta-degree profile;
- comparison levels: pointwise representative, aggregate representative, balanced sign-compatible, and hull/log-volume;
- endpoint audits for the 3.11.5 $\Rightarrow$ 3.12 comparison chart;
- nonarchimedean and archimedean (Ind3) local orientations;
- ordered real-line alignment with cancellation only after scale equality;
- a canonical unit-scale ordered alignment from a nonarchimedean (Ind3) entry;
- a bridge from factored square/full-label SHE obligations to the Hodge-descent (Ind3) route.

5 Current Lean Results

The current first-pass experiment report evaluates to:

<code>orderedRealLineRouteTheoremAvailable</code>	<code>= true,</code>
<code>nonarchimedeanEntryCanonicalAlignmentTheoremAvailable</code>	<code>= true,</code>
<code>factoredSHEBridgeTheoremAvailable</code>	<code>= true,</code>
<code>mismatchCounterexampleBlocksRawCancellation</code>	<code>= true,</code>
<code>labelIndependentJ2CollapseRejectedInZModModel</code>	<code>= true,</code>
<code>representativeJ2SignQuotientDescentRejectedInZModModel</code>	<code>= true,</code>
<code>absLabelThetaDegreeHalfRangeModelAvailable</code>	<code>= true,</code>
<code>balancedLevelRejectedAtFinalRouteTheoremAvailable</code>	<code>= true,</code>
<code>disputeSettledByCurrentStage</code>	<code>= false.</code>

The theorem-level route is:

nonarch. (Ind3) entry	$\rightarrow$	canonical ordered $\mathbb{R}$ -alignment	$\rightarrow$	source/target alignment
		$\downarrow$		$\downarrow$
factored SHE transport	$\rightarrow$	Hodge-descent audit	$\rightarrow$	$q_{\text{signed}} \leq \Theta_{\text{signed}}$.

The route remains conditional on the displayed hypotheses.

6 Audit Findings

No formal statement currently proves IUT III, Corollary 3.12 from Mochizuki’s published hypotheses. The strongest positive result is conditional: if the nonarchimedean (Ind3) entry, ordered real-line alignment, and Hodge/SHE square-weight transport audit are supplied, then Lean checks the final signed q -to- Θ inequality.

The strongest negative result is also limited: in the current $\mathbb{F}_\ell$ -label model, Lean rejects a single label-independent scale accounting for all representative j^2 factors, and it rejects balanced sign-compatible evidence as the final hull/log-volume comparison level. Lean also rejects direct descent of arbitrary raw representative j^2 theta-degree data to $|F_\ell|$, while accepting the half-range exponent convention stated in IUT II.

One correctness issue was fixed during this audit. The experiment report fields were renamed so that they describe theorem availability under hypotheses rather than an unconditional mathematical fact.

7 Missing Mathematics

The present code does not yet formalize:

- initial Θ -data as in IUT I;
- actual Hodge theaters, Frobenioids, prime strips, log-shells, or Θ -links;
- the Hodge–Arakelov theta evaluation and Gaussian monoids of IUT II;
- the construction of the IUT II theta values and Gaussian monoids which should supply the present $|F_\ell|$ -exponent data;
- the full multiradial construction of IUT III, Theorem 3.11;

- the genuine holomorphic hull and determinant operations of Step (xi);
- the exact IUT IV log-volume estimates and Diophantine applications;
- a proof that the current Hodge/SHE transport obligations follow from Mochizuki’s full hypotheses.

8 Next Work

The next significant formal step is not another wrapper. It is to replace current explicit Hodge/SHE transport assumptions by constructions closer to the papers:

$$\begin{aligned}
 & \text{theta values } q^{j^2} \\
 & \rightsquigarrow \text{Gaussian monoids} \\
 & \rightsquigarrow \text{square/full-label preservation} \\
 & \rightsquigarrow \text{hull/log-volume route.}
 \end{aligned}$$

Only after this bridge is formalized can the first-pass experiment begin to test the actual mathematical load-bearing part of Mochizuki’s response to Scholze–Stix.
